(54) Title: METHOD AND APPARATUS FOR REPLACING A MITRAL VALVE WITH A STENTLESS BIOPROSTHETIC VALVE HAVING CHORDAE

(57) Abstract: A stentless bioprosthetic valve includes at least one piece of biocompatible material comprising a bi-leaflet conduit having a proximal end and a distal end. The proximal end defines a first annulus for suturing to the valve annulus in the heart. The conduit includes first and second leaflets that mimic the native anterior and posterior leaflets and extend between the ends of the conduit. The distal end defines a second annulus at which the first and second leaflets terminate. The conduit further includes first and second pairs of prosthetic chordae projecting from the leaflets at the second annulus. Each of the prosthetic chordae comprises a solid uninterrupted extension of the piece of biocompatible material. One of the first pair of prosthetic chordae extends from the first leaflet and has a distal end for suturing to one of the two papillary muscles and the other of the first pair of prosthetic chordae extends from the first leaflet and has a distal end for suturing to the other of the two papillary muscles. One of the second pair of prosthetic chordae extends from the second leaflet and has a distal end for suturing to one of the two papillary muscles and the other of the second pair of prosthetic chordae extends from the second leaflet and has a distal end for suturing to the other of the two papillary muscles. A method for replacing the native mitral valve with a stentless bioprosthetic valve is also provided.

**METHOD AND APPARATUS FOR REPLACING A MITRAL VALVE
WITH A STENTLESS BIOPROSTHETIC VALVE HAVING CHORDAE**

Related Application

This application claims priority from U.S.
5 provisional patent application Serial No. 60/417,912,
filed on October 10, 2002, the subject matter of which
is incorporated herein by reference.

Technical Field

The present invention relates to a method and
10 apparatus for replacing a native mitral valve with a
stentless bioprosthetic valve having prosthetic
chordae.

Background of the Invention

The mitral valve is a functional unit composed of
15 multiple dynamically interrelated units. During
cardiac cycle, the fibrous skeleton, the anterior and
posterior leaflets, the papillary muscles, the chordae

-2-

tendinea, and the ventricular and atrial walls all interplay symphonically to render a competent valve. The complex interaction between the mitral valve and the ventricle by the subvalvular apparatus (the

5 papillary muscles and the chordae tendinea) is essential in that it maintains the continuity between the atrio-ventricular ring (which is part of the fibrous skeleton of the heart) and the ventricular muscle mass, which is essential for the normal function

10 of the mitral valve.

The chordae tendinea, which connect the valve leaflets to the papillary muscles (PM) act like "tie rods" in an engineering sense. Not only do the chordae tendinea prevent prolapse of the mitral valve leaflets

15 during systole, but they also support the left ventricular muscle mass throughout the cardiac cycle.

To function adequately, the mitral valve needs to open to a large orifice area and, for closure, the mitral leaflets need to have an excess of surface area

20 (i.e. more than needed to effectively close the mitral orifice). On the other hand, systolic contraction of the posterior ventricular wall around the mitral annulus (MA) creates a mobil D-shaped structure with sphincter-like function which reduces its area by

-3-

approximately 25 % during systole, thus exposing less of the mitral leaflets to the stress of the left ventricular pressure and flow.

Although the primary function of the mitral valve
5 is to act as a one-way no return valve, it has been postulated that the structural integrity of the MA-PM continuity is essential for normal left ventricular function.

Since it was first suggested in the mid-1960's
10 that preservation of the subvalvular apparatus during mitral valve replacement might prevent low cardiac output in the early postoperative period, this important observation was largely overlooked by most surgeons for many years.

15 There is now considerable laboratory and clinical evidence to corroborate this position, as evidence has demonstrated that chordal excision is associated with a change in left ventricular shape from oval to spherical, which can lead to a significant increase in
20 postoperative left ventricular end systolic volume and wall stress, along with a decline in ejection fraction.

The majority of evidence appears to support the concept that preservation of the subvalvular apparatus with the MA-PM continuity in any procedure on the

-4-

mitral valve is important for the improved long-term quality and quantity of life after mitral valve surgery. Reparative techniques to correct mitral valve disease are often the best surgical approach for

5 dealing with mitral valve abnormalities, however mitral valvuloplasty is not always feasible because of extensive fibrosis, leaflets calcification, or massive chordal rupture. Mitral valve replacement using either a mechanical valve or a bioprosthetic valve thus

10 remains the best surgical solution for severe mitral valve disease.

However, there are many additional problems that face patients after valve replacement with a prosthetic valve. Valve-related problems include limitation of

15 the mitral flow (due to a small effective orifice area) during exercise and high cardiac output imposed by a smaller size artificial valve as compared with the natural valve orifice area.

Further, the rigid structure of an artificial

20 valve prevents the physiologic contraction of the posterior wall of the left ventricle surrounding the MA during systole. Surgical interruption of the MA-PM continuity accounts for changes in geometry mechanics and performance of the left ventricle. Myocardial

-5-

rupture, a lethal complication of mitral valve replacement, results from excision or stretching of the papillary muscle in a thin and fragile left ventricle. Myocardial rupture can also be caused by a strut of a
5 stented bioprosthetic valve eroding into or protruding through the posterior left ventricle wall. Maintaining the MA-PM continuity appears to provide a substantial degree of protection from this devastating complication. Also, the difficulties in controlling
10 adequate anticoagulation for a mechanical valve bring a high morbidity risk factor of thromboembolic and hemorrhagic complication and endocarditis.

Stented tissue valves, although less thrombogenic, are not reliably durable and, because of the rigid
15 stent, they are less hemodynamically efficient. Stentless valves are considered to have the potential advantages of superior hemodynamic performance and enhanced durability and have already showed satisfactory mid-term results in the aortic position.
20 From these points of view, it is expected that new stentless valves in the mitral position will be developed. However, stentless mitral valves are not yet commonly available for clinical use because of the anatomical and functional complexity of the mitral

-6-

valve and the subvalvular apparatus, resulting in the difficulties of the design and implantation procedures of the stentless mitral valves. The present invention provides an apparatus and method for replacing a
5 native mitral valve with a stentless, bioprosthetic valve that maintains the anatomical and functional complexity of the mitral valve and the subvalvular apparatus.

Summary of the Invention

10 The present invention is a stentless bioprosthetic valve for replacing a native mitral valve resected from a valve annulus in a heart. The native mitral valve has anterior and posterior leaflets and associated native chordae tendineae. The bioprosthetic valve
15 comprises at least one piece of biocompatible material comprising a bi-leaflet conduit having dimensions that correspond to the dimensions of the native mitral valve. The conduit has a proximal end and a distal end. The proximal end of the conduit defines a first
20 annulus for suturing to the valve annulus in the heart. The conduit includes first and second leaflets that mimic the three-dimensional anatomical shape of the anterior and posterior leaflets of the native mitral valve. The first and second leaflets extend between

-7-

the proximal end and the distal end of the conduit.

The distal end of the conduit defines a second annulus at which the first and second leaflets terminate. The conduit further includes first and second pairs of

5 prosthetic chordae projecting from the first and second leaflets at the second annulus. Each of the prosthetic chordae comprises a solid uninterrupted extension of the at least one piece of biocompatible material. The first and second pairs of prosthetic chordae provide

10 prolapse prevention for the bioprosthetic valve and support the left ventricular muscle throughout the cardiac cycle. One of the first pair of prosthetic chordae extends from the first leaflet and has a distal end for suturing to one of the two papillary muscles

15 and the other of the first pair of prosthetic chordae extends from the first leaflet and has a distal end for suturing to the other of the two papillary muscles. One of the second pair of prosthetic chordae extends from the second leaflet and has a distal end for

20 suturing to one of the two papillary muscles and the other of the second pair of prosthetic chordae extends from the second leaflet and has a distal end for suturing to the other of the two papillary muscles.

-8-

In accordance with one aspect of the invention, the at least one piece of biocompatible material comprises harvested biological tissue.

In accordance with another aspect of the invention, the harvested biological tissue comprises pericardial tissue.

In accordance with yet another aspect of the invention, the at least one piece of biocompatible material comprises an artificial tissue.

In accordance with another feature of the invention, the bioprosthetic valve further comprises a biocompatible, unstented ring connected to the first annulus for supporting the first annulus and for suturing to the valve annulus of the heart. The ring, when sutured to the valve annulus, impedes dilatation of the valve annulus and preserves motion of the valve annulus.

The present invention also provides a method for replacing a native mitral valve having anterior and posterior leaflets with a stentless bioprosthetic valve. According to the inventive method, at least one piece of biocompatible material that comprises a bi-leaflet conduit having dimensions that correspond to the dimensions of the native mitral valve being

-9-

replaced is provided. The conduit has a proximal end and a distal end. The proximal end defines a first annulus and the distal end defines a second annulus. The conduit further includes first and second leaflets

5 that mimic the three-dimensional shape of the anterior and posterior leaflets of the native mitral valve. The first and second leaflets extend from the proximal end and terminate at the distal end of the conduit. The conduit further includes first and second pairs of

10 prosthetic chordae projecting from the first and second leaflets at the second annulus. Each of the prosthetic chordae comprises a solid uninterrupted extension of the at least one piece of biocompatible material. The entire native mitral valve is resected from the valve

15 annulus. A distal end of one of the first pair of prosthetic chordae that extends from the first leaflet is sutured to one of the two papillary muscles. A distal end of the other of the first pair of prosthetic chordae that extends from the first leaflet is sutured

20 to the other of the two papillary muscles. A distal end of one of the second pair of prosthetic chordae that extends from the second leaflet is sutured to one of the two papillary muscles. A distal end of the other of the second pair of prosthetic chordae that

-10-

extends from the second leaflet is sutured to the other
of the two papillary muscles. The first annulus of the
conduit is sutured to the valve annulus of the native
mitral valve to secure the bioprosthetic valve to the
5 valve annulus. The first and second pairs of
prosthetic chordae provide prolapse prevention and left
ventricular muscle support functions for the
bioprosthetic valve and assist the bioprosthetic valve
in maintaining the continuity between the valve annulus
10 and the papillary muscles.

In accordance with another aspect of the inventive
method, a biocompatible, unstented support ring
encircles the first annulus. The support ring is
sutured to the valve annulus of the heart to secure the
15 bioprosthetic valve to the valve annulus and to impede
dilatation of the valve annulus and preserve motion of
the valve annulus.

Brief Description of the Drawings

The foregoing and other features of the present
20 invention will become apparent to those skilled in the

Description of Embodiments

The present invention relates to a method and
apparatus for replacing a native mitral valve with a
stentless bioprosthetic valve having prosthetic
15 chordae. As representative of the present invention,
Fig. 1 illustrates an apparatus 10 comprising a
stentless bioprosthetic valve 12 for replacing a native
mitral valve 14 (Fig. 4).

The bioprosthetic valve 12 shown in Figs. 1 and 2
20 is made from one or more pieces of biocompatible
material formed into a bi-leaflet conduit 20 having
dimensions that correspond to the dimensions of the
native mitral valve 14. The conduit 20 has a proximal
end 22 and a distal end 24. The proximal end 22

-13-

defines a first annulus 26 for suturing to the valve annulus of the native mitral valve 14, as described further below.

5 The conduit 20 further includes first and second leaflets 30 and 32 that mimic the three-dimensional anatomical shape of the anterior and posterior leaflets 34 and 36 (Fig. 4), respectively, of the native mitral valve 14. The first and second leaflets 30 and 32 extend between the proximal end 22
10 and the distal end 24 of the conduit 20. The distal end 24 of the conduit 20 defines a second annulus 38 at which the first and second leaflets 30 and 32 terminate.

15 The conduit 20 further includes first and second pairs 40 and 42, respectively, of prosthetic chordae 44 that project from the first and second leaflets 30 and 32 at the second annulus 38. Each of the prosthetic chordae 44 comprises a solid uninterrupted extension of the at least one piece of biocompatible
20 material. Each of the first pair 40 of prosthetic chordae 44 has a distal end 46 and each of the second pair 42 of prosthetic chordae has a distal end 48.

 The biocompatible material of the bioprosthesis valve 12 may be a harvested biological material

-14-

including, but not limited to, bovine pericardial tissue, horse pericardial tissue, or porcine pericardial tissue. The biocompatible material may also be suitable synthetic material including, but not limited to, polyurethane or expanded PTFE.

In the case of, for example, bovine pericardial tissue, the tissue is harvested in slaughterhouses and kept in cold saline solution for transport to minimize the effects of autolysis and bacterial/enzymatic reactions on the tissue. The pericardial tissue is dissected to be clean of all fatty and other biological materials. The pericardial material is then formed into a tri-dimensional shape of what will be the leaflet structure of the bioprosthesis valve 12 by attaching the pericardial tissue to a mold (not shown) having such a shape. The pericardial material is also trimmed to roughly form the four prosthetic chordae 44 that extend from the distal end 24 of the conduit 20.

The molds are produced in different sizes to render valves of different sizes to match the needs of the different patients (i.e., sizes between 23 and 35 mm in diameter). The molds can have either a male shape of what will be the inflow aspect of the valve 12, or a female aspect of the same. The

-15-

pericardial tissue is applied to the molds and accommodated to ensure the complete conformability to the mold's shape. The bioprosthetic valve 12 can be made with only one piece of pericardial tissue, as shown in Figs. 1 and 2. Alternatively, the bioprosthetic valve 12 can be made with two pieces of pericardial tissue, one of which will form the first leaflet 30 and the other forms the second leaflet 32 of the prosthetic valve, as may be seen in Fig. 2A.

Once the pericardial piece(s) is fully conformed on the mold, the biological material is tanned by immersion in an adequate fixation solution (e.g. 0.65% glutaraldehyde solution buffered at pH 7.4). This tanning can be achieved with an ample range of glutaraldehyde concentrations (e.g. between 0.4% and 5%).

When the pericardial tissue is already fixed with the fixation agent, it is then separated from the mold and the lateral edges 50 and 52 (Fig. 2) are sutured together along a seam 54 to form the tubular conduit 20. In the alternate embodiment of Fig. 2A where two pieces of pericardial tissue are used, it is necessary to suture the tissue in two locations, thereby forming two seams 56 and 58. The seams 54, 56,

-16-

and 58 are always placed at what will be the commissures of the prosthetic valve 12, where the first leaflet 30 meets the second leaflet 32.

In accordance with one embodiment of the present invention, the valve 12 further includes a flexible, unstented, biocompatible ring 60 (Fig. 3) that is sutured about the first annulus 26 along a proximal edge 62 at the proximal end 22 of the conduit 20. The ring 60 is for supporting the first annulus 26 and for suturing the valve 12 to the valve annulus in the heart. The ring 60 may be made from a biological material such as, for example, bovine or porcine pericardial tissue, or from a suitable synthetic material, such as the material marketed under the tradename DACRON or the material marketed under the tradename TEFLON. In the embodiment of Fig. 3, the ring 60 is positioned underneath the proximal edge 62 of the conduit 20. Alternatively, the ring 60 could be positioned on top of the proximal edge 62, as shown in Fig. 3A, or wrapped around the proximal edge, as shown in Fig. 3B, and subsequently sutured in place.

According to an alternate construction for the valve 12 shown in Fig. 3C, a ring 70 is formed at the proximal end 22 of the conduit 20 by folding an

-17-

additional portion 72 of the conduit 20 located at the proximal end 22 over onto itself and suturing the folded portion to the conduit.

Replacement of the native mitral valve 14 (Fig. 4) with the bioprosthetic valve 12 begins by taking either direct or echocardiographic measurements of the height of the anterior and posterior leaflets 34 and 36 of the native mitral valve. The size of the bioprosthetic valve 12 to be implanted is determined based on a measurement of the distance between the right and left trigones on the valve annulus. The distal ends 46 and 48 of the first and second pairs 40 and 42, respectively, of the prosthetic chordae 44 may be trimmed to adjust the height of the valve 12 based on the measurements taken. Four stay-sutures (6-0 silk) may be placed on the annulus of both mitral commissures and on the centers of the anterior and posterior leaflets 34 and 36 to help make sure that the bioprosthetic valve 12 is implanted in the proper anatomical orientation.

As may be seen in Fig. 4, the native mitral valve 14 is then dissected from the heart. The proximal end 80 of the native mitral valve 14 is resected from the valve annulus 82. At the distal

-18-

end 84 of the native mitral valve 14, the anterior and posterior leaflets 34 and 36 are resected in such a manner that the free edges 86 and 88 of the anterior and posterior leaflets, respectively, remain intact and
5 connected to the native chordae tendinea 90 which, in turn, remain attached to the papillary muscles 100 and 102. The native chordae tendinea 90 are left intact, at least temporarily, because they are helpful in handling the papillary muscles 100 during
10 implantation of the valve 12.

Next, the prosthetic valve 12 is moved into the position shown in Fig. 5. The distal end 46 of the first pair 40 of prosthetic chordae 44 that extends from the first leaflet 30 is sutured to the papillary
15 muscle 100. On the same commissural side of the valve 12, the distal end 48 of the second pair 42 of prosthetic chordae 44 that extends from the second leaflet 32 is also sutured to the papillary muscle 100. This suture, indicated by the reference number 110, may
20 be a 4-0 Ethibond mattress suture with a pledget (not shown). The suture 110 extends through the distal ends 46 and 48 of both of the prosthetic chordae 44 and attaches to the papillary muscle 100 at a single location as shown in Fig. 5. Alternatively, the

-19-

suture 110 may be threaded through one of the distal ends 46 and 48 of the prosthetic chordae 44 to attach it to the papillary muscle 100 at one location, and then threaded through the distal end of the other
5 prosthetic chordae to attach it to the papillary muscle 100 at another location. It is further contemplated that a separate suture 110 could be used to attach each of the distal ends 46 and 48 of the prosthetic chordae to the papillary muscle 100.

10 The same procedure is then performed on the opposite commissural side of the valve 12. The distal end 46 of the first pair 40 of prosthetic chordae 44 that extends from the first leaflet 30 is sutured to the papillary muscle 102. Further, the distal end 48
15 of the second pair 42 of prosthetic chordae 44 that extends from the second leaflet 32 is also sutured to the papillary muscle 102. This suture, indicated by the reference number 112, may be a 4-0 Ethibond mattress suture with a pledget (not shown). The
20 suture 112 extends through the distal ends 46 and 48 of both of the prosthetic chordae 44 and attaches to the papillary muscle 102 at a single location as shown in Fig. 5. Alternatively, the suture 112 may be threaded through one of the distal ends 46 and 48 of the

-20-

prosthetic chordae 44 to attach it to the papillary muscle 102 at one location, and then threaded through the distal end of the other prosthetic chordae to attach it to the papillary muscle 102 at another location. It is further contemplated that a separate suture 112 could be used to attach each of the distal ends 46 and 48 of the prosthetic chordae to the papillary muscle 102.

Following the attachment of the four prosthetic chordae 44 to the papillary muscles 100 and 102, the dissected free edges 86 and 88 of the native anterior and posterior leaflets and the native chordae tendinea 90 are then excised as shown in Fig. 6.

To complete the replacement procedure, the ring 60 at the proximal end 22 of the bioprosthetic valve 12 is sewn to the native mitral annulus 82 as shown in Figs. 7 and 8 with sutures 120. Proper anatomical orientation of the valve 12 in the valve annulus 82 is aided by the four stay-sutures that were placed on the annulus of both mitral commissures and on the centers of the anterior and posterior leaflets 34 and 36. The sutures 120 may be three 4-0 Prolene running sutures or other suitable means. Once it is sutured to the valve annulus 82, the ring 60 functions to impede dilatation

-21-

of the valve annulus and preserve the motion of the valve annulus.

The prosthetic valve 12 and associated method for replacing the native mitral valve 14 described above
5 are useful in treating degenerative myxomatous valve with chordal rupture and annular dilatation, rheumatic valve disease, degenerative calcific mitral valve stenosis, infected mitral valve endocarditis and unsuccessful mitral valve repair.

10 With the distal ends 46 and 48 of the prosthetic chordae 44 being sutured to the papillary muscles 100 and 102, the prosthetic chordae are able to provide prolapse prevention and left ventricular muscle support functions. Significantly, the bioprosthetic valve 12
15 and the method for implanting the bioprosthetic valve described herein accomplish the goal of maintaining the continuity between the valve annulus 82 and the papillary muscles 100 and 102.

Additional benefits of the bioprosthetic valve 12
20 and associated method for implanting include:

A) a large orifice with an adequate circumference correlated with the size of the patient's body surface area, unrestrictive to a central free flow, compatible with high cardiac

-22-

output at exercise, a low pressure required to open the valve, and without an increased gradient across the valve;

5 B) rapid opening and closure at all pressure ranges, without regurgitate flow and obstruction of the left ventricle outflow tract;

10 C) no rigid support or stent in the mitral area to allow the physiologic contraction of the left ventricular posterior wall around the mitral annulus during systole, flexible to adapt precisely to the mitral annulus reducing the tissue stress and allowing a uniform distribution of stress on the prosthetic valve which provides longer life and a higher resistance to wear, tear,
15 and calcification; and

F) anticoagulation treatment is not required and no trauma of the blood elements is produced.

From the above description of the invention, those skilled in the art will perceive improvements, changes
20 and modifications. Such improvements, changes and modifications within the skill of the art are intended to be covered by the appended claims.

-23-

Having described the invention, we claim:

1. A stentless bioprosthesis valve for replacing a native mitral valve resected from a valve annulus in a heart, the native mitral valve having anterior and posterior leaflets and associated native chordae tendinea, said bioprosthesis valve comprising:

at least one piece of biocompatible material comprising a bi-leaflet conduit having dimensions that correspond to the dimensions of the native mitral valve, said conduit having a proximal end and a distal end, said proximal end of said conduit defining a first annulus for suturing to the valve annulus in the heart;

said conduit including first and second leaflets that mimic the three-dimensional anatomical shape of the anterior and posterior leaflets of the native mitral valve, said first and second leaflets extending between said proximal end and said distal end of said conduit, said distal end of said conduit defining a second annulus at which said first and second leaflets terminate;

said conduit further including first and second pairs of prosthetic chordae projecting from said first and second leaflets at said second annulus, each of

-24-

said prosthetic chordae comprising a solid
uninterrupted extension of said at least one piece of
biocompatible material, said first and second pairs of
prosthetic chordae providing prolapse prevention for
5 the bioprosthetic valve and supporting the left
ventricular muscle throughout the cardiac cycle;

one of said first pair of prosthetic chordae
extending from said first leaflet and having a distal
end for suturing to one of the two papillary muscles
10 and the other of said first pair of prosthetic chordae
extending from said first leaflet and having a distal
end for suturing to the other of the two papillary
muscles;

one of said second pair of prosthetic chordae
15 extending from said second leaflet and having a distal
end for suturing to one of the two papillary muscles
and the other of said second pair of prosthetic chordae
extending from said second leaflet and having a distal
end for suturing to the other of the two papillary
20 muscles.

2. The bioprosthetic valve of claim 1 wherein
said at least one piece of biocompatible material
comprises harvested biological tissue.

-25-

3. The bioprosthetic valve of claim 2 wherein said harvested biological tissue comprises pericardial tissue.

4. The bioprosthetic valve of claim 1 wherein said at least one piece of biocompatible material comprises an artificial tissue.

5. The bioprosthetic valve of claim 1 further comprising a biocompatible, unstented ring connected to said first annulus for supporting said first annulus and for suturing to the valve annulus in the heart, said ring, when sutured to the valve annulus, impeding dilatation of the valve annulus and preserving motion of the valve annulus.

6. The bioprosthetic valve of claim 5 wherein said ring is formed from said at least one piece of biocompatible material that has been folded over itself and sutured at the proximal end of said conduit.

-26-

7. The bioprosthetic valve of claim 5 wherein said ring is a separate piece of biocompatible material that is sutured about said first annulus.

8. The bioprosthetic valve of claim 7 wherein said ring comprises a synthetic material.

9. The bioprosthetic valve of claim 7 wherein said ring comprises harvested biological tissue.

10. A stentless bioprosthetic valve for replacing a native mitral valve resected from a valve annulus in a heart, the native mitral valve having anterior and posterior leaflets and associated native chordae tendinea, said bioprosthetic valve comprising:

at least one piece of biocompatible material comprising a bi-leaflet conduit having dimensions that correspond to the dimensions of the native mitral valve, said conduit having a proximal end and a distal end, said proximal end of said conduit defining a first annulus for suturing to the valve annulus in the heart;

said conduit including first and second leaflets that mimic the three-dimensional anatomical shape of the anterior and posterior leaflets of the native

-27-

mitral valve, said first and second leaflets extending
between said proximal end and said distal end of said
conduit, said distal end of said conduit defining a
second annulus at which said first and second leaflets
5 terminate;

said conduit further including first and second
pairs of prosthetic chordae projecting from said first
and second leaflets at said second annulus, each of
said prosthetic chordae comprising a solid
10 uninterrupted extension of said at least one piece of
biocompatible material, said first and second pairs of
prosthetic chordae providing prolapse prevention for
the bioprosthetic valve and supporting the left
ventricular muscle throughout the cardiac cycle;

15 one of said first pair of prosthetic chordae,
extending from said first leaflet and having a distal
end for suturing to one of the two papillary muscles
and the other of said first pair of prosthetic chordae
extending from said first leaflet and having a distal
20 end for suturing to the other of the two papillary
muscles;

one of said second pair of prosthetic chordae
extending from said second leaflet and having a distal
end for suturing to one of the two papillary muscles

-28-

and the other of said second pair of prosthetic chordae extending from said second leaflet and having a distal end for suturing to the other of the two papillary muscles; and

a biocompatible, unstented ring connected to said first annulus for supporting said first annulus and for suturing to the valve annulus in the heart, said ring, when sutured to the valve annulus, impeding dilatation of the valve annulus and preserving motion of the valve annulus.

11. The bioprosthetic valve of claim 10 wherein said at least one piece of biocompatible material comprises harvested biological tissue.

12. The bioprosthetic valve of claim 11 wherein said harvested biological tissue comprises pericardial tissue.

13. The bioprosthetic valve of claim 10 wherein said at least one piece of biocompatible material comprises an artificial tissue.

-29-

14. A method for replacing a native mitral valve having anterior and posterior leaflets with a stentless bioprosthetic valve, said method comprising the steps of:

5 providing at least one piece of biocompatible material that comprises a bi-leaflet conduit having dimensions that correspond to the dimensions of the native mitral valve being replaced, the conduit having a proximal end and a distal end, the proximal end
10 defining a first annulus and the distal end defining a second annulus, the conduit further including first and second leaflets that mimic the three-dimensional shape of the anterior and posterior leaflets of the native mitral valve, the first and second leaflets extending
15 from the proximal end and terminating at the distal end of the conduit, the conduit further including first and second pairs of prosthetic chordae projecting from the first and second leaflets at the second annulus, each of the prosthetic chordae comprising a solid
20 uninterrupted extension of the at least one piece of biocompatible material;

 resecting the native mitral valve from the valve annulus;

-30-

suturing a distal end of one of the first pair of prosthetic chordae that extends from the first leaflet to one of the two papillary muscles;

5 suturing a distal end of the other of the first pair of prosthetic chordae that extends from the first leaflet to the other of the two papillary muscles;

suturing a distal end of one of the second pair of prosthetic chordae that extends from the second leaflet to one of the two papillary muscles;

10 suturing a distal end of the other of the second pair of prosthetic chordae that extends from the second leaflet to the other of the two papillary muscles; and

suturing the first annulus of the conduit to the valve annulus of the native mitral valve to secure the bioprosthetic valve to the valve annulus;

15 whereby the first and second pairs of prosthetic chordae provide prolapse prevention and left ventricular muscle support functions for the bioprosthetic valve and assist the bioprosthetic valve in maintaining the continuity between the valve annulus and the papillary muscles.

20

-31-

15. The method of claim 14 further comprising the steps of:

providing a biocompatible, unstented support ring that encircles the first annulus; and

suturing the support ring to the valve annulus of the heart to secure the bioprosthetic valve to the valve annulus and to impede dilatation of the valve annulus and preserve motion of the native mitral valve annulus.

16. The method of claim 15 wherein said step of providing a support ring includes the steps of:

folding a portion of the biocompatible material at the proximal end of the conduit over onto itself; and

suturing the folded portion to the conduit about the first annulus.

17. The method of claim 15 wherein said step of providing a support ring includes the steps of:

providing a separate ring-shaped piece of biocompatible material; and

suturing the ring-shaped piece about said first annulus.
